FIDELITY INSTITUTIONAL INSIGHTS

Capital Market Assumptions: A Comprehensive Global Approach for the Next 20 Years

We believe that asset returns over the next 20 years will be lower than their long-term averages, with stocks outperforming bonds and emerging markets generating the highest returns

KEY TAKEAWAYS

- Our long-term capital market assumption for U.S. equities is below long-term average returns due to lower growth potential and higher starting valuations.
- Emerging-markets stocks represent the most attractive area for public market return expectations due to favorable growth prospects and better starting valuations.
- Fixed income return expectations are higher compared with 2021 due to higher starting bond yields.
- Higher-than-expected inflation likely would hurt most equity and fixed income returns, with long-duration nominal fixed income facing the most risk from higher inflation.
- One scenario that could boost equity returns is continued central bank induced financial repression, which could keep real rates low and support higher valuations relative to historical averages.

FIDELITY CANADA INSTITUTIONAL™

Expectations based on our 2022 capital market assumptions¹

EXHIBIT 1: EM equities have the highest real return potential over the long term.

Fidelity Secular CMA Return and Volatility Estimates

ASSET CLASS	REAL RETURNS	VOLATILITY
Emerging Market Equities	5.1%	23%
Global Equities ex-USA (MSCI ACWI ex-U.S.)	3.7%	18%
U.S. High Yield	3.3%	11%
Developed Market (ex-U.S.) Equities	3.3%	19%
U.S. Equities	3.0%	17%
Commodities (BCOM)	2.1%	21%
Developed non-U.S. Bonds USD Hedged	2.0%	5%
IG Bonds (Bloomberg Barclays U.S. Aggregate)	1.9%	7%
Municipal Bonds	1.4%	7%
Developed non-U.S. Sovereign Debt USD Hedged	1.4%	5%
U.S. 10yr Treasury Bond	1.3%	9%
U.S. TIPS	1.0%	8%
U.S. 30 Year Treasury Bond	0.6%	11%
U.S. Cash	-0.2%	3%

Our CMAs are forward-looking estimates but are not presented as investment recommendations or guarantees of actual future performance.

Volatility: standard deviation of returns. See appendix for index details. Real returns are geometric annualized average return expectations over 20 years, adjusted for inflation. Source: Fidelity Investments (AART), as of 4/30/22.

U.S. Equities

- For U.S. stocks, we expect a 3% annualized real return through 2042, less than half the 6.6% average since 2001 and the 7.1% advance since 1926. Our 20-year real return estimate declined from 3.1% in 2021. Risk-adjusted return estimates remain lower than their historical norms.
- Valuations for U.S. stocks remain elevated compared with the rest of the world. We believe they will converge closer to those of other developed markets over time.
- Compared with 2021 we see reduced earnings potential for U.S. stocks as higher rates increase corporate interest expenses. Offsetting this negative, we note that the decline for the U.S. stock market in the early half of 2022 resulted in more-attractive starting valuations.

U.S. Bonds

- We expect bond markets to produce a real return of 1.9% annualized over the next 20 years, vs. 2.1% a year historically (since 1926). This estimate rose from 1.5% in 2021, largely influenced by higher yields that increased the attractiveness of new bond investments.
- One meaningful risk is that higher-than-expected inflation over the next two decades could reduce the returns of long-duration nominal fixed-income assets, such as 30-year Treasury bonds.
- Partly reflecting increased interest rate and inflation risks, we expect bonds to produce a lower Sharpe ratio relative to the past two decades.

Emerging Markets

- Emerging equities represent the most promising area in the public markets, due to our expectations for higher real GDP growth and low starting valuations.
- We anticipate a 5.1% real return for emerging markets in the next 20 years, compared with a 6.1% real return over the past two decades.

Developed Markets (ex-U.S.)

- We expect most non-U.S. developed countries, including Australia, Canada, the UK, France, Germany, and Japan, to lag the real GDP growth of the U.S. through 2042, mainly due to birth rates and other demographic trends. This is expected to keep earnings growth subdued relative to the U.S. and emerging markets.
- Return estimates for developed-equity markets outside the U.S. are 3.3% in real terms over the next 20 years, topping U.S. stocks. We expect a diminished return for developed non-U.S. markets versus the long-term historical average, and slightly higher volatility compared with the U.S., based on a higher concentration of more-cyclical sectors.

U.S. Bonds vs. U.S. Stocks

We expect the lower return environment will result in less attractive risk-adjusted returns for global equities compared with the historical average, with Sharpe ratios remaining relatively even across core stock and bond categories (Exhibit 2).

Our forecasts place the 1.1% expected gap between the real returns of U.S. equities and U.S. investment-grade bonds over the next 20 years in the 7th percentile relative to history, which is significantly lower than the previous two decades (Exhibit 3).

A higher rate of inflation could increase this performance gap going forward and coincide with higher correlations between stocks and bonds.

EXHIBIT 2: Risk-adjusted return estimates for equities are now lower than their historical levels.

Historical and Forecasted Geometric Average Returns

REAL ANNUALIZED RETURNS	20-YEAR FORECAST	LAST 20 YEARS	LONG-TERM HISTORY
U.S. Equity	3.0%	6.6%	7.1%
Developed Markets (ex-U.S.)	3.3%	3.8%	5.3%
Emerging Markets	5.1%	6.1%	4.5%
Investment-Grade Bonds	1.9%	1.3%	2.1%
Cash/Short-Term Debt	-0.2%	-1.2%	0.4%

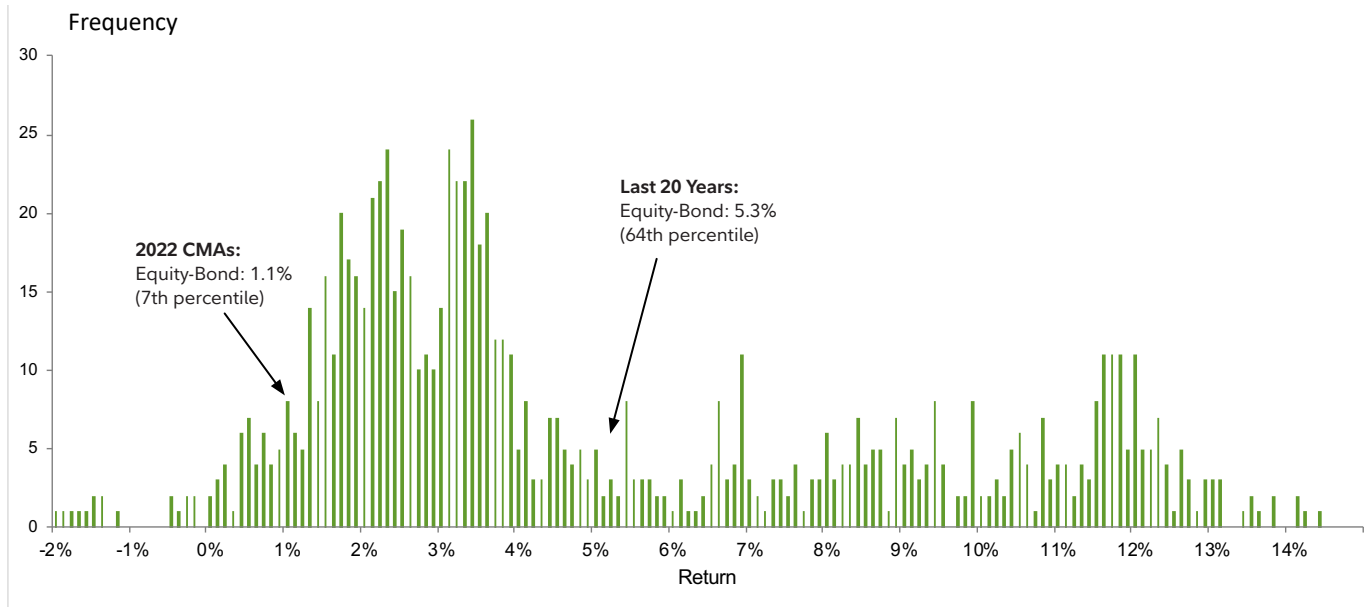

Historical and Forecasted Sharpe Ratios

Real annualized returns calculated as geometric average returns. Long-term history: since 1926. Sharpe ratio compares portfolio returns above the risk-free rate relative to overall portfolio volatility, with a higher Sharpe ratio implying better risk-adjusted returns. Past performance is no guarantee of future results. You cannot invest directly in an index. Asset-class total returns are represented by indexes from the following sources: Fidelity Investments, Morningstar, MSCI, Bloomberg Finance LLP. Source: Fidelity Investments proprietary analysis of historical asset class returns, as of 4/30/22.

EXHIBIT 3: Over the next 20 years, we expect U.S. equities to outperform bonds by a smaller margin than they did during the past 20 years.

U.S. Equity Excess Returns over Investment-Grade Bonds (1926–2022)

Past performance is no guarantee of future results. U.S. Equities—Dow Jones U.S. Total Stock Market Index; Investment-Grade Bonds—Bloomberg U.S. Aggregate Bond Index. Source: Fidelity Investments (AART), as of 4/30/22.

EXHIBIT 4: Varied yield and valuation scenarios could result in different realized U.S. equity returns.

U.S. Equity CMA Yield and Valuation Scenarios

20-Year Annualized Real Geometric Average Returns

Source: Fidelity Investments, as of 4/30/22.

Scenario analysis: Other factors could lead to higher or lower returns

Our CMAs are 20-year estimates. We acknowledge a range of outcomes can influence returns, volatility levels, and asset correlations. In the next few exhibits, we illustrate how realized returns can differ from our forecasts and explore some of the key factors driving the differences. These scenarios include shifts in growth and inflation regimes, and financial repression from central banks.

Exhibit 4 illustrates how varied yield and valuation scenarios could lead to higher U.S. equity returns over the next several decades. For example, if interest rates (U.S. Treasury yields) remain at roughly 2022 levels over the next 20 years, U.S. equities would gain an additional 1.7% per year, as a lower interest expense would boost earnings.

If valuations do not revert lower, as they do in our estimates, equity returns would be 2.1% higher on an annual basis.

While these factors are correlated and may not result in a real U.S. equity return of 6.8%, this example is meant to emphasize how different macro scenarios could lead to varied outcomes.

The Impact of Inflation on Returns and Correlations

Inflation is a prime example of how varying yield and valuation trajectories can impact our CMAs (Exhibit 5). Higher inflation tends to weigh on the real returns of both stocks and bonds—especially bonds.

- Within fixed income categories, higher inflation often corresponds with more inflation uncertainty, which tends to increase nominal bond yields and bring down real returns.
- On the equity side, the upward pressure that inflation puts on interest rates can drag on returns by bringing down valuations, increasing interest expense, and reducing the incentive to use leverage. All three factors can hamper profit margins and earnings potential.
- Higher inflation often benefits commodities, largely due to higher real returns.

Inflation also impacts the correlation between different asset classes. For example, when inflation is elevated, stocks and bonds tend to have positive correlations, and commodities often have lower correlations to equities. For these reasons, owning inflation hedges as part of a strategic asset allocation, such as TIPS, commodities, and real assets, can be beneficial. Our base case scenario is for inflation to remain around 2.5%, which we expect would keep the stock/bond correlation negative. However, if we experience higher inflation over the next two decades, stock/bond correlations would likely turn positive, rising most significantly for longer-duration bonds (Exhibit 6).

EXHIBIT 5: High inflation is a drag on real returns, especially for nominal fixed income.

Asset Class CMA Inflation Scenarios

Source: Fidelity Investments as of 4/30/2022.

EXHIBIT 6: Higher inflation may increase stock/bond correlations.

	LOW INFLATION REGIME	HIGH INFLATION REGIME	CHANGE
Investment Grade-Bonds	20%	32%	↑
30-Year Treasuries	8%	22%	↑
10-Year Treasuries	1%	17%	↑
TIPS	-6%	-6%	—
Commodities	5%	-5%	↓

U.S. Equities—MSCI USA Index; Investment-Grade Bonds—Bloomberg U.S. Aggregate Bond Index; TIPS—Bloomberg U.S. Treasury Inflation Protected Notes; Bloomberg Commodity Index. Source: Fidelity Investments (AART), as of 4/30/22.

No matter the asset class, this study showed that higher inflation tends to be associated with a greater uncertainty of capital market outcomes. This underscores the potential benefit of inflation hedges, such as TIPS and commodities, as part of a multi-asset portfolio.

Financial repression: A wild card

Financial repression refers to monetary and regulatory actions that artificially suppress real (inflation-adjusted) interest rates. These policy moves help fulfill government objectives, although they can hurt savers.

- **Equities:** By suppressing real yields, financial repression tends to boost equity performance, primarily by boosting equity valuations and suppressing interest expense.
- **Fixed Income:** The impact of financial repression on fixed income is contingent on the inflation regime. If inflation is high, we would expect nominal yields to rise, impairing bond performance.

Our analysis suggests that financial repression tends to increase the relative performance of stocks versus

bonds, whether policy actions result in a high-or low-inflation regime. Also, if inflation were to surprise to the upside, we would expect stocks to outperform bonds by a wider margin (Exhibit 7).

Since the range of potential outcomes is more uncertain during financial repression, strategic asset allocation decisions are essential to help mitigate unforeseen outcomes. This includes maintaining long-term exposure to real assets and non-U.S. equities to provide diversification.

Details of our CMA Framework and Philosophy

The following section provides greater detail regarding our methodology for estimating asset-class returns, volatility, and correlations.

Our Beliefs

Long-term capital market assumptions (CMAs) can serve as valuable inputs for investment decisions. These assumptions can help financial advisors position their clients to reach their long-term goals; assist

EXHIBIT 7: Financial repression tends to increase the expected performance gap between stocks and bonds, with higher inflation lowering asset-return estimates.

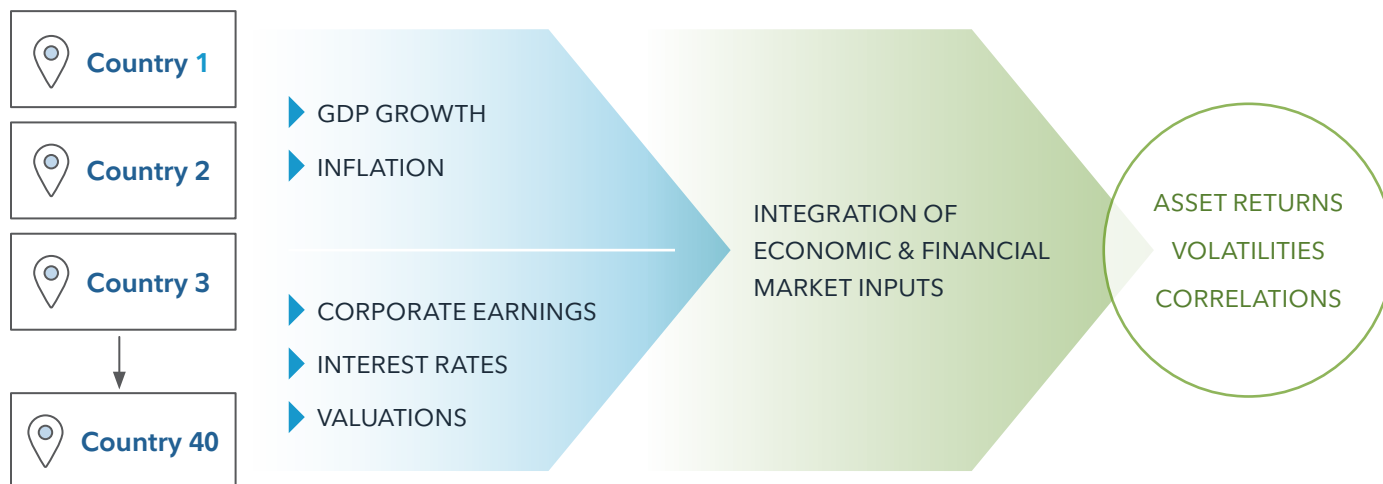

Asset Class CMA Financial Repression Scenarios

20-Year Annualized Real Geometric Average Returns

EXHIBIT 8: Our CMA process is global, forward-looking, and dynamic.

For illustrative purposes only. Source: Fidelity Investments (AART).

institutional money managers in making strategic asset allocation decisions; and aid pension fund managers in creating assumptions on equity returns and interest rates to aid pension managers in supporting their decisions for managing defined benefit plans.

Our CMA framework focuses on the specifics of how economic and financial market inputs influence asset returns over long periods of time (Exhibit 8). While other approaches assume the connection between GDP growth and asset returns is either perfect or nonexistent, our framework is built on the following beliefs:

- There is a principal relationship between economic trends and asset-class performance.
- By deriving country-specific assumptions, we generate estimates that are global and adaptive across diverse economies and asset categories.

What makes our capital market assumptions different

We focus on a 20-year horizon to build our secular (long-term) CMAs to align with investment planning and portfolio construction considerations.

While secular CMAs are intended primarily for strategic allocation decisions, we develop other types of forecasts for shorter-horizon decisions. As an example, our business cycle research focuses on economic trends, which form a basis for return and volatility patterns over shorter time horizons to add value through active asset allocation. (See our “Quarterly Market Update” and “Business Cycle Update” series for more details.)

We develop 20-year forecasts because asset returns often deviate significantly from long-term historical averages, providing opportunity for forward-looking estimates to add to an investment process. Since 1926, 20-year real (inflation-adjusted) equity market returns have averaged 7%, but have ranged from 0% to 14% due to differences in the economic growth and inflation landscape, valuations, and the interest rate environment.

We believe our CMA research process provides a better sense of whether the next 20 years will be on the high or low end of historical outcomes. We therefore incorporate the core themes of global GDP growth with a deep consideration of the current capital market composition.

A Global Perspective

Lastly, by adapting to today's global environment, in which developing countries account for a growing share of the world economy and the investment universe, our approach avoids the limitations of backward-looking data that can be dominated by the history of the U.S. and other developed markets.

Our multidimensional, scalable approach—based on fundamentals such as growth, earnings, and valuation—can be applied to diverse economies to provide the building blocks for CMAs at the country, sector, and sub-asset-class level. The 20-year time horizon is flexible enough to capture shifts in the economic and market landscape, but stable enough to serve as assumptions for long-term investment strategies.

By focusing on the specifics of how GDP growth and assets returns are related—and how they differ—our approach avoids the overly simplistic assumptions of some CMA frameworks.

Our Forward-Looking Approach

A dynamic blending of market composition, profit margins, interest rates, debt levels, inflation, and our first-in-class GDP growth forecasts can produce a thoughtful forward-looking view that limits the dependence on historical averages. The basis for our asset return and volatility assumptions is our 20-year forecast of gross domestic product (GDP) growth for the 40 largest countries in the MSCI All Country World Index, described in the Fidelity article, "Secular Outlook for Global Growth: the Next 20 Years." Our forecasts are based on a panel approach that synthesizes trends across multiple countries. We believe this approach makes our forecasts more robust than those derived from individual country data.

Return assumptions: A blend of economic and financial measures

We believe the current environment of low yields and the shift to lower-trend GDP growth will result in lower fixed income returns relative to history. Our secular rate outlook is based on the strong relationship between GDP and bond yields, since faster-growing

economies are supported by more productive investment that justifies higher borrowing costs. Empirically, there have been deviations from this relationship during financial booms and subsequent busts, but over longer time horizons, higher rates of nominal GDP growth have generally coincided with higher interest rates.

Fixed income

We base our fixed income return expectations on the assumption that sovereign—or government—bond yields will gravitate toward the rate of nominal economic growth in the long term. Specifically, we assume that the yield on 10-year U.S. Treasury bonds will converge nonlinearly to our nominal GDP forecast of 4.2% annually over a 20-year time horizon (Exhibit 9).

Government bonds: We believe falling bond prices will be a drag on future returns as yields rise over time, with longer-duration bonds expected to produce the lowest returns.² As yields rise, positive returns from higher coupon income—in addition to roll-down returns achieved as bonds mature along a positively sloped yield curve—could help offset the price depreciation, resulting in our estimate of 1.3% annualized real return for a constant maturity 10-year Treasury note and 0.6% for a constant maturity 30-year Treasury bond.³

Investment-grade bonds: The returns to credit-sensitive bonds are a function of both the "risk-free" rate calculated for government bonds and the additional return potentially generated by the credit spread, which compensates investors for the uncertainty and default risk of corporate bonds.⁴ We also adjust returns to match the duration of the investment-grade bond universe, which is around 6.5 years.⁵ Using these assumptions, we arrived at our estimate of a 1.9% return for the Bloomberg Aggregate Bond Index over the next 20 years.⁶ (Exhibit 1).

Cash/Short-term debt: Given our estimated government bond yields, we then calculate term premia to forecast potential returns of short-maturity government securities.⁷ We form a forward-looking view of the yield curve by linking our term premia

EXHIBIT 9: Government bond yields and GDP growth have been highly correlated over the long term.

Nominal GDP Growth vs. Sovereign Bond Yields, 1985–2022

GDP: Gross Domestic Product. Source: Official country estimates, Haver Analytics, Bloomberg Finance LLP, Fidelity Investments (AART), as of 4/30/22.

expectations to country-specific histories and the uncertainty about future growth and inflation, as reflected in the dispersion of forecasts among market observers. Due to the very short duration of cash, price depreciation from rising yields will be minimal, while the convergence to higher yields over time can increase coupon returns. However, current negative real yields are a considerable drag on cash, resulting in a real return estimate of -0.2%, which would fail to outpace inflation over the next 20 years.

Equities

Corporate earnings growth is the bedrock of our forward equity view. We model future earnings growth by linking GDP growth and financial market inputs and then incorporate a forward-looking valuation estimate that is not based on historical averages.

Earnings: We base our earnings expectations on GDP growth prospects adjusted for the industry mix of the equity market, to reflect the productivity rates specific to the universe of publicly traded companies, rather

than the productivity rate of the overall economy. For example, the equity market-capitalization weight of the highly productive U.S. technology sector significantly exceeds its weight in GDP, which implies that the productivity of the equity market exceeds overall economic productivity.⁸ Also, interest rates and leverage are a significant driver of earnings growth. For example, higher leverage increases the return on equity while lower interest rates reduce interest costs, providing a boost to earnings expectations over the 20-year horizon. Rising longer-term market yields from mid-2020 through mid-2022 have reduced our market assumptions for equities.

Valuations: We develop estimates based on the key drivers of a country's cyclically adjusted price-to-earnings (CAPE) multiple, such as market composition, growth, and inflation, rather than assuming that valuations will revert to historical averages. For instance, higher inflation rates tend to increase uncertainty and risk premia, resulting in lower valuations. Also, a larger weight of high-valuation industries such as technology boosts valuations.

For the U.S., we expect the CAPE to average 20x over the next 20 years, which is above its long-term average of 17x earnings. In the aggregate, our worldwide valuation estimates for the next 20 years are higher than historical averages, reflecting the increased importance of high-productivity industries and continued credibility of global central banks in containing inflationary pressures.

Whether a country's equity market return will be boosted or hindered by repricing back to this long-term trend also depends on starting valuations.⁹ The CAPE for the U.S. stock market was 31x earnings, well above our long-term expectations as of April 30, 2022 (Exhibit 10). Outside the U.S., equity valuations were lower, but still expensive relative to our expectations.

EXHIBIT 10: We expect U.S. equity valuations to converge lower over the next 20 years.

Shiller CAPE vs. Forward U.S. Equity Returns

Past performance is no guarantee of future results. It is not possible to invest directly in an index. All indexes are unmanaged. See Appendix for important index information. Price-to-earnings (P/E) ratio (or multiple): stock price divided by earnings per share, which indicates how much investors are paying for a company's earnings power. Cyclically adjusted earnings are 10-year averages adjusted for inflation. Source: FactSet, Haver Analytics, Fidelity Investments (AART), as of 4/30/22.

Equity return expectations: Overall, we expect domestic and non-U.S. equities to have lower returns over the next 20 years as a result of slower global growth and elevated valuations. There are, however, some key differences across different segments of the market. We expect U.S. equities to trail the returns of both developed-markets equities outside the U.S. and emerging market equities (Exhibit 1).

Volatility and correlations

We built a forward-looking process for forecasting volatilities and correlations using a regime-based simulation engine.¹⁰ We use historical data to simulate return paths starting from a secular and cyclical state most closely resembling the current environment. As of April 2022, our starting secular state is low growth and a mix of high and low inflation, and our starting cyclical state is a mix of mid- and late cycle. We take a core set of asset classes with relatively reliable historical data beginning in the 1950s and identify these core assets as factors. For non-core asset classes, we can estimate factor exposures and calculate a covariance matrix using 20-year simulations of the secular state, starting from today's starting conditions and using a transition matrix to account for the potential transitions to a different growth or inflation regime.

In contrast, most attempts at portfolio optimization are conducted using asset correlations that are calculated from past historical returns, for which there is limited history for newer asset classes such as emerging-market equities and global sovereign debt. We believe there are shortcomings to this approach, as asset correlations can change over time. During the past 60 years, the 20-year correlation between U.S. equities and investment-grade bonds ranged from -0.1 to 0.4. At a given point in time, whether inflation or growth is the more dominant factor will influence correlations. When inflation is low and stable, growth has a greater impact on correlations. Because stock performance is positively tied to changes in growth expectations, while bond returns are inversely related, investment-grade bond returns tend to have a low or

even negative correlation with equity returns in a low-inflation environment. By contrast, when inflation is higher and more volatile—as it was in the 1970s—the correlation between stocks and bonds increased.

Relative return conclusions

Following are some of our key findings when comparing our return, volatility, and correlation estimates:

- We expect stocks and bonds to have lower real returns relative to the last 20 years and vs. their long-term histories.
- We anticipate risk-adjusted returns for U.S. and developed-market equity categories to be lower than long-term historical levels.
- We expect bonds to have a much lower Sharpe ratio relative to the past two decades.

- Although higher inflation expectations increase stock/bond correlations, we expect bonds to remain a good diversifier against equity returns.
- Under the different scenarios we ran to explore the impact inflation, financial repression, and other factors on our CMAs, we continue to expect stocks to outperform bonds.

As with any financial planning or portfolio construction process, comparing relative returns across asset categories is essential. Although we expect asset returns will be lower than they have been historically, our base case is for equities to outperform bonds over the next 20 years.

Appendix

Asset classes shown in Exhibit 1 are represented by the following indexes: Emerging-Market Stocks—MSCI Emerging Markets Index; Global Equities ex. U.S.—MSCI All Country World Index (ACWI) ex USA Index; Developed Market ex. U.S. Equities—MSCI World ex USA Index; U.S. Equities—Dow Jones U.S. Total Stock Market Index; U.S. High-Yield Bonds—ICE Bank of America (BofA) U.S. High Yield Index; Investment-Grade Bonds—Bloomberg U.S. Aggregate Bond Index; Developed Market Non-U.S. Bonds USD Hedged—Bloomberg Global Aggregate ex USD Total Return Index Value Hedged USD; Municipal Bonds—Bloomberg Municipal Bond Index; U.S. TIPS—Bloomberg U.S. Treasury Inflation Protected Notes; Developed Market Non-U.S. Sovereign Debt USD Hedged—Bloomberg Global Treasury DM ex US 30% EUR 10% Country Cap Total Return Index Hedged USD; U.S. Cash/Short-Term—Bloomberg 1-3 Month US Treasury Bill Index.

Index Definitions

Bloomberg Global Aggregate ex USD Total Return Index Value Hedged USD measures the performance of global investment-grade debt from 24 local currency markets. It is a multi-currency index that includes fixed-rate treasury, government-related, corporate, and securitized bonds from developed- and emerging-market issuers while excluding U.S.-denominated debt.

Bloomberg Global Treasury DM ex US 30% EUR 10% Country Cap Total Return Index Hedged USD measures the total return of fixed-rate, local currency government debt of investment-grade developed-market countries (excluding the United States), hedged to USD. The index maintains 30% exposure to eurozone countries and includes a 10% country cap.

Bloomberg Commodity Index measures the performance of the commodities market. It is calculated on an excess return basis and reflects commodity futures price movements.

Bloomberg 1-3 Month US Treasury Bill Index is designed to measure the performance of public obligations of the U.S. Treasury that have a remaining maturity of greater than or equal to 1 month and less than 3 months.

Bloomberg Municipal Bond Index is a market value-weighted index of investment-grade municipal bonds with maturities of one year or more.

Bloomberg U.S. Aggregate Bond Index is an unmanaged, market value-weighted performance benchmark for investment-grade fixed-rate debt issues, including government, corporate, asset-backed, and mortgage-backed securities with maturities of at least one year.

Bloomberg U.S. Treasury Inflation Protected Notes Index is a market value-weighted index that measures the performance of inflation-protected securities issued by the U.S. Treasury.

Consumer Price Index (CPI) is an inflationary indicator that measures the change in the cost of a fixed basket of products and services, including housing, electricity, food, and transportation.

Dow Jones U.S. Total Stock Market IndexSM is a full market capitalization-weighted index of all equity securities of U.S.-headquartered companies with readily available price data.

ICE BofA U.S. High Yield Index is a market capitalization-weighted index of U.S. dollar-denominated, below-investment-grade corporate debt publicly issued in the U.S. market.

MSCI ACWI (All Country World Index) ex USA Index is a market capitalization-weighted index designed to measure investable equity market performance for global investors of large and mid cap stocks in developed and emerging markets, excluding the United States.

MSCI Emerging Markets (EM) Index is a market capitalization-weighted index designed to measure the investable equity market performance for global investors in emerging markets.

MSCI® Europe, Australasia, Far East Index (EAFE) is an unmanaged, market capitalization-weighted index designed to represent the performance of developed stock markets outside the U.S. and Canada.

S&P 500[®] is an unmanaged, market capitalization-weighted index of common stocks and a registered service mark of The McGraw-Hill Companies, Inc., which has been licensed for use by Fidelity Distributors Corporation and its affiliates.

Endnotes

¹ Past performance is not a guarantee of future results. All historical performance data quoted is as of 4/30/22, unless otherwise noted.

² Duration estimates a bond's change in price given a change in interest rates, assuming a parallel shift in the yield curve (neither steepening nor flattening).

³ The roll-down return is the gain (loss) caused by a falling (rising) yield when a bond approaches its maturity date. Therefore, as bonds approach their maturity date, they should roll down the positively sloped yield curve to a lower yield, creating a gain.

⁴ Treasury securities are considered "risk free" because they are backed by the full faith and credit of the U.S. government.

⁵ As of Apr. 30, 2022.

⁶ The composition of the combined investment-grade bond portfolio has a similar weighting of government and corporate bonds as the Bloomberg U.S. Aggregate Bond Index. Investment-grade bonds are bonds rated BBB-/Baa3/BBB- or higher by Standard & Poor's/Moody's/Fitch.

⁷ The term premium is the excess yield that investors require to commit to holding a long-term bond instead of a series of shorter-term bonds.

⁸ Source: Bureau of Economic Analysis, Haver Analytics, Fidelity Investments (AART) as of Apr. 30, 2022.

⁹ We define current valuations as today's cyclically adjusted P/E ratio, or the Shiller CAPE, which is the ratio of today's stock market index price divided by the average of the last 10 years of operating earnings per share.

¹⁰ Correlation measures interdependencies between two random variables, with coefficients indicating perfect negative correlation at -1, absence of correlation at 0, and perfect positive correlation at +1.

Investment decisions should be based on an individual's own goals, time horizon, and tolerance for risk. Nothing in this content should be considered to be legal or tax advice, and you are encouraged to consult your own lawyer, accountant, or other advisor before making any financial decision.

Stock markets are volatile and can fluctuate significantly in response to company, industry, political, regulatory, market, or economic developments. Foreign markets can be more volatile than U.S. markets due to increased risks of adverse issuer, political, market, or economic developments, all of which are magnified in emerging markets. These risks are particularly significant for investments that focus on a single country or region.

Although bonds generally present less short-term risk and volatility than stocks, bonds do contain interest rate risk (as interest rates rise, bond prices usually fall, and vice versa) and the risk of default, or the risk that an issuer will be unable to make income or principal payments.

Additionally, bonds and short-term investments entail greater inflation risk—or the risk that the return of an investment will not keep up with increases in the prices of goods and services—than stocks. Increases in real interest rates can cause the price of inflation-protected debt securities to decrease.

Investing involves risk, including risk of loss.

For institutional use only.

This is original content from Fidelity Investments in the U.S. No recipient is authorized to pass this communication on to any other person whatsoever or reproduce it by any means without the prior written consent of Fidelity.

This document is used by Fidelity Investments Canada ULC ("FIC") and is not meant to endorse or sponsor any specific Fidelity product or service. FIC investment funds are advised by our investment division, Fidelity Canada Investment Management, or sub-advised by a variety of companies, such as Fidelity Management & Research Company LLC, FIAM LLC, FIL Limited, Geode Capital Management LLC and State Street Global Advisors Ltd. Mutual funds, ETFs and other investment products and services that are sponsored by FIC are only qualified for sale in the provinces and territories of Canada.

These materials may contain statements that are "forward-looking statements," which are based on certain assumptions of future events. Forward-looking statements are based on information available on the date hereof, and Fidelity Investments Canada ULC ("FIC") does not assume any duty to update any forward-looking statement. Actual events may differ from those assumed by FIC when developing forward-looking statements. There can be no assurance that forward-looking statements, including any projected returns, will materialize or that actual market conditions and/or performance results will not be materially different or worse than those presented.

Information provided in this document is for informational and educational purposes only. To the extent any investment information in this material is deemed to be a recommendation, it is not meant to be impartial investment advice or advice in a fiduciary capacity and is not intended to be used as a primary basis for you or your client's investment decisions. Fidelity and its representatives may have a conflict of interest in the products or services mentioned in this material because they have a financial interest in them, and receive compensation, directly or indirectly, in connection with the management, distribution, and/or servicing of these products or services, including Fidelity funds, certain third-party funds and products, and certain investment services.

Information presented herein is for discussion and illustrative purposes only and is not a recommendation or an offer or solicitation to buy or sell any securities. Views expressed are as of 7/31/22, based on the information available at that time, and may change based on market and other conditions. Unless otherwise noted, the opinions provided are those of the authors and not necessarily those of Fidelity Investments or its affiliates. Fidelity does not assume any duty to update any of the information. • Investment decisions should be based on an individual's own goals, time horizon, and tolerance for risk. Nothing in this content should be considered to be legal or tax advice, and you are encouraged to consult your own lawyer, accountant, or other advisor before making any financial decision. • In general, the bond market is volatile, and fixed income securities carry interest rate risk. (As interest rates rise, bond prices usually fall, and vice versa. This effect is usually more pronounced for longer-term securities.) • Fixed income securities carry inflation, credit, and default risks for both issuers and counterparties.

Investing involves risk, including risk of loss.

Past performance is no guarantee of future results. An investment may be risky and may not be suitable for an investor's goals, objectives and risk tolerance. Investors should be aware that an investment's value may be volatile and any investment involves the risk that you may lose money. Performance results for individual accounts will differ from performance results for composites and representative accounts due to factors such as portfolio size, account objectives and restrictions, and factors specific to a particular investment structure.

Diversification and asset allocation do not ensure a profit or guarantee against loss.

Third party trademarks and service marks are the property of their respective owners. All other trademarks and service marks are the property of Fidelity Investments Canada ULC or its affiliated companies. FIC does not provide legal or tax advice and we encourage you to consult your own lawyer, accountant or other advisor before making an investment.
